

Chapter 4

Shared Memory Programming with Pthreads

Roadmap

- Problems programming shared memory systems.
- Controlling access to a critical section.
- Thread synchronization.
- Programming with POSIX threads.
- Mutexes.
- Producer-consumer synchronization and semaphores.
- Barriers and condition variables.
- Read-write locks.
- Thread safety.

A Shared Memory System

Processes and Threads

- A process is an instance of a running (or suspended) program.
- Threads are analogous to a “light-weight” process.
- In a shared memory program a single process may have multiple threads of control.

POSIX® Threads

- Also known as Pthreads.
- A standard for Unix-like operating systems.
- A library that can be linked with C programs.
- Specifies an application programming interface (API) for multi-threaded programming.

Caveat

- The Pthreads API is only available on POSIXR systems — Linux, MacOS X, Solaris, HPUX, ...

Hello World! (1)

```
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>

/* Global variable: accessible to all threads */
int thread_count;

void *Hello(void* rank); /* Thread function */

int main(int argc, char* argv[]) {
    long          thread; /* Use long in case of a 64-bit system */
    pthread_t* thread_handles;

    /* Get number of threads from command line */
    thread_count = strtol(argv[1], NULL, 10);

    thread_handles = malloc (thread_count*sizeof(pthread_t));
```

declares the various Pthreads functions, constants, types, etc.

Hello World! (2)

```
for (thread = 0; thread < thread_count; thread++)  
    pthread_create(&thread_handles[thread], NULL,  
        Hello, (void*) thread);  
  
printf("Hello from the main thread\n");  
  
for (thread = 0; thread < thread_count; thread++)  
    pthread_join(thread_handles[thread], NULL);  
  
free(thread_handles);  
return 0;  
} /* main */
```

Hello World! (3)

```
void *Hello(void* rank) {  
    long my_rank = (long) rank;  /* Use long in case of 64-bit system */  
  
    printf("Hello from thread %ld of %d\n", my_rank, thread_count);  
  
    return NULL;  
} /* Hello */
```

Compiling a Pthread program

```
gcc -g -Wall -o pth_hello pth_hello . c -lpthread
```

link in the Pthreads library

Running a Pthreads program

```
. / pthread_hello <number of threads>
```

```
. / pthread_hello 1
```

Hello from the main thread

Hello from thread 0 of 1

```
. / pthread_hello 4
```

Hello from the main thread

Hello from thread 0 of 4

Hello from thread 1 of 4

Hello from thread 2 of 4

Hello from thread 3 of 4

Global variables

- Can introduce subtle and confusing bugs!
- Limit use of global variables to situations in which they're really needed.
 - Shared variables.

Starting the Threads

- Processes in MPI are usually started by a script.
- In Pthreads the threads are started by the program executable.

Starting the Threads

pthread.h

**One object for
each thread.**

pthread_t

```
int pthread_create (  
    pthread_t* thread_p /* out */,  
    const pthread_attr_t* attr_p /* in */,  
    void* (*start_routine) ( void ) /* in */,  
    void* arg_p /* in */ );
```

pthread_t objects

- Opaque
- The actual data that they store is system-specific.
- Their data members aren't directly accessible to user code.
- However, the Pthreads standard guarantees that a pthread_t object does store enough information to uniquely identify the thread with which it's associated.

A closer look (1)

```
int pthread_create (  
    pthread_t* thread_p /* out */,  
    const pthread_attr_t* attr_p /* in */,  
    void* (*start_routine) ( void ) /* in */,  
    void* arg_p /* in */ );
```

We won't be using, so we just pass NULL.

Allocate before calling.

A closer look (2)

```
int pthread_create (  
    pthread_t* thread_p /* out */,  
    const pthread_attr_t* attr_p /* in */,  
    void* (*start_routine) ( void ) /* in */,  
    void* arg_p /* in */ );
```

Pointer to the argument that should
be passed to the function *start_routine*.

The function that the thread is to run.

Function started by pthread_create

- Prototype:
`void* thread_function (void* args_p) ;`
- Void* can be cast to any pointer type in C.
- So args_p can point to a list containing one or more values needed by thread_function.
- Similarly, the return value of thread_function can point to a list of one or more values.

Running the Threads

Main thread forks and joins two threads.

Stopping the Threads

- We call the function `pthread_join` once for each thread.
- A single call to `pthread_join` will wait for the thread associated with the `pthread_t` object to complete.

a_{00}	a_{01}	\cdots	$a_{0,n-1}$
a_{10}	a_{11}	\cdots	$a_{1,n-1}$
\vdots	\vdots		\vdots
a_{i0}	a_{i1}	\cdots	$a_{i,n-1}$
\vdots	\vdots		\vdots
$a_{m-1,0}$	$a_{m-1,1}$	\cdots	$a_{m-1,n-1}$

x_0
x_1
\vdots
x_{n-1}

 $=$

y_0
y_1
\vdots
$y_i = a_{i0}x_0 + a_{i1}x_1 + \cdots a_{i,n-1}x_{n-1}$
\vdots
y_{m-1}

MATRIX-VECTOR MULTIPLICATION IN PTHREADS

Serial pseudo-code

```
/* For each row of A */  
for (i = 0; i < m; i++) {  
    y[i] = 0.0;  
    /* For each element of the row and each element of x */  
    for (j = 0; j < n; j++)  
        y[i] += A[i][j]* x[j];  
}
```

$$y_i = \sum_{j=0}^{n-1} a_{ij}x_j$$

Using 3 Pthreads

Thread	Components of y
0	y[0], y[1]
1	y[2], y[3]
2	y[4], y[5]

thread 0

```
y[0] = 0.0;  
for (j = 0; j < n; j++)  
    y[0] += A[0][j]* x[j];
```

general case

```
y[i] = 0.0;  
for (j = 0; j < n; j++)  
    y[i] += A[i][j]*x[j];
```

Pthreads matrix-vector multiplication

```
void *Pth_mat_vect(void* rank) {
    long my_rank = (long) rank;
    int i, j;
    int local_m = m/thread_count;
    int my_first_row = my_rank*local_m;
    int my_last_row = (my_rank+1)*local_m - 1;

    for (i = my_first_row; i <= my_last_row; i++) {
        y[i] = 0.0;
        for (j = 0; j < n; j++)
            y[i] += A[i][j]*x[j];
    }

    return NULL;
} /* Pth_mat_vect */
```

CRITICAL SECTIONS

Estimating π

$$\pi = 4 \left(1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots + (-1)^n \frac{1}{2n+1} + \cdots \right)$$

```
double factor = 1.0;
double sum = 0.0;
for (i = 0; i < n; i++, factor = -factor) {
    sum += factor/(2*i+1);
}
pi = 4.0*sum;
```

Using a dual core processor

	n			
	10^5	10^6	10^7	10^8
π	3.14159	3.141593	3.1415927	3.14159265
1 Thread	3.14158	3.141592	3.1415926	3.14159264
2 Threads	3.14158	3.141480	3.1413692	3.14164686

Note that as we increase n , the estimate with one thread gets better and better.

A thread function for computing π

```
void* Thread_sum(void* rank) {
    long my_rank = (long) rank;
    double factor;
    long long i;
    long long my_n = n/thread_count;
    long long my_first_i = my_n*my_rank;
    long long my_last_i = my_first_i + my_n;

    if (my_first_i % 2 == 0) /* my_first_i is even */
        factor = 1.0;
    else /* my_first_i is odd */
        factor = -1.0;

    for (i = my_first_i; i < my_last_i; i++, factor = -factor) {
        sum += factor/(2*i+1);
    }

    return NULL;
} /* Thread_sum */
```

Possible race condition

```
y = Compute(my rank);  
x=x+y;
```

Time	Thread 0	Thread 1
1	Started by main thread	
2	Call Compute ()	Started by main thread
3	Assign y = 1	Call Compute ()
4	Put x=0 and y=1 into registers	Assign y = 2
5	Add 0 and 1	Put x=0 and y=2 into registers
6	Store 1 in memory location x	Add 0 and 2
7		Store 2 in memory location x

Busy-Waiting

- A thread repeatedly tests a condition, but, effectively, does no useful work until the condition has the appropriate value.
- Beware of optimizing compilers, though!

```
y = Compute(my_rank);  
while (flag != my_rank);  
x = x + y;  
flag++;
```

flag initialized to 0 by main thread

Pthreads global sum with busy-waiting

```
void* Thread_sum(void* rank) {
    long my_rank = (long) rank;
    double factor;
    long long i;
    long long my_n = n/thread_count;
    long long my_first_i = my_n*my_rank;
    long long my_last_i = my_first_i + my_n;

    if (my_first_i % 2 == 0)
        factor = 1.0;
    else
        factor = -1.0;

    for (i = my_first_i; i < my_last_i; i++, factor = -factor) {
        while (flag != my_rank);
        sum += factor/(2*i+1);
        flag = (flag+1) % thread_count;
    }

    return NULL;
} /* Thread_sum */
```

Global sum function with critical section after loop (1)

```
void* Thread_sum(void* rank) {  
    long my_rank = (long) rank;  
    double factor, my_sum = 0.0;  
    long long i;  
    long long my_n = n/thread_count;  
    long long my_first_i = my_n*my_rank;  
    long long my_last_i = my_first_i + my_n;  
  
    if (my_first_i % 2 == 0)  
        factor = 1.0;  
    else  
        factor = -1.0;
```

Global sum function with critical section after loop (2)

```
for (i = my_first_i; i < my_last_i; i++, factor = -factor)
    my_sum += factor/(2*i+1);

while (flag != my_rank);
sum += my_sum;
flag = (flag+1) % thread_count;

return NULL;
} /* Thread_sum */
```

Mutexes

- A thread that is busy-waiting may continually use the CPU accomplishing nothing.
- Mutex (mutual exclusion) is a special type of variable that can be used to restrict access to a critical section to a single thread at a time.

Mutexes

- Used to guarantee that one thread “excludes” all other threads while it executes the critical section.
- The Pthreads standard includes a special type for mutexes: `pthread_mutex_t`.

```
int pthread_mutex_init(  
    pthread_mutex_t*      mutex_p      /* out */  
    const pthread_mutexattr_t* attr_p    /* in  */);
```

Mutexes

- When a Pthreads program finishes using a mutex, it should call

```
int pthread_mutex_destroy(pthread_mutex_t* mutex_p /* in/out */);
```

- In order to gain access to a critical section a thread calls

```
int pthread_mutex_lock(pthread_mutex_t* mutex_p /* in/out */);
```

Mutexes

- When a thread is finished executing the code in a critical section, it should call

```
int pthread_mutex_unlock(pthread_mutex_t* mutex_p /* in/out */);
```

Global sum function that uses a mutex (1)

```
void* Thread_sum(void* rank) {  
    long my_rank = (long) rank;  
    double factor;  
    long long i;  
    long long my_n = n/thread_count;  
    long long my_first_i = my_n*my_rank;  
    long long my_last_i = my_first_i + my_n;  
    double my_sum = 0.0;  
  
    if (my_first_i % 2 == 0)  
        factor = 1.0;  
    else  
        factor = -1.0;
```

Global sum function that uses a mutex (2)

```
for (i = my_first_i; i < my_last_i; i++, factor = -factor) {  
    my_sum += factor/(2*i+1);  
}  
pthread_mutex_lock(&mutex);  
sum += my_sum;  
pthread_mutex_unlock(&mutex);  
  
return NULL;  
} /* Thread_sum */
```

Threads	Busy-Wait	Mutex
1	2.90	2.90
2	1.45	1.45
4	0.73	0.73
8	0.38	0.38
16	0.50	0.38
32	0.80	0.40
64	3.56	0.38

$$\frac{T_{\text{serial}}}{T_{\text{parallel}}} \approx \text{thread_count}$$

Run-times (in seconds) of π programs using $n = 108$ terms on a system with two four-core processors.

Time	flag	Thread				
		0	1	2	3	4
0	0	crit sect	busy wait	susp	susp	susp
1	1	terminate	crit sect	susp	busy wait	susp
2	2	—	terminate	susp	busy wait	busy wait
⋮	⋮			⋮	⋮	⋮
?	2	—	—	crit sect	susp	busy wait

Possible sequence of events with busy-waiting and more threads than cores.

PRODUCER-CONSUMER SYNCHRONIZATION AND SEMAPHORES

Issues

- Busy-waiting enforces the order threads access a critical section.
- Using mutexes, the order is left to chance and the system.
- There are applications where we need to control the order threads access the critical section.

Problems with a mutex solution

```
/* n and product_matrix are shared and initialized by the main thread */  
/* product_matrix is initialized to be the identity matrix */  
void* Thread_work(void* rank) {  
    long my_rank = (long) rank;  
    matrix_t my_mat = Allocate_matrix(n);  
    Generate_matrix(my_mat);  
    pthread_mutex_lock(&mutex);  
    Multiply_matrix(product_mat, my_mat);  
    pthread_mutex_unlock(&mutex);  
    Free_matrix(&my_mat);  
    return NULL;  
} /* Thread_work */
```

For example, suppose each thread generates an $n \rightarrow n$ matrix, and we want to multiply the matrices together in thread-rank order.

Since matrix multiplication isn't commutative, our mutex solution would have problems:

A somewhat more complicated example involves having each thread “send a message” to another thread.

A first attempt at sending messages using pthreads

```
/* messages has type char**. It's allocated in main. */
/* Each entry is set to NULL in main. */
void *Send_msg(void* rank) {
    long my_rank = (long) rank;
    long dest = (my_rank + 1) % thread_count;
    long source = (my_rank + thread_count - 1) % thread_count;
    char* my_msg = malloc(MSG_MAX*sizeof(char));

    sprintf(my_msg, "Hello to %ld from %ld", dest, my_rank);
    messages[dest] = my_msg;

    if (messages[my_rank] != NULL)
        printf("Thread %ld > %s\n", my_rank, messages[my_rank]);
    else
        printf("Thread %ld > No message from %ld\n", my_rank, source);

    return NULL;
} /* Send_msg */
```

We could fix the problem with a busy-wait while statement:

```
while (messages[my rank] == NULL);
printf("Thread %ld > %s\n", my rank, messages[my rank]);
```

Syntax of the various semaphore functions

```
#include <semaphore.h>
```

← Semaphores are not part of Pthreads;
you need to add this.

```
int sem_init(  
    sem_t*      semaphore_p    /* out */,  
    int         shared         /* in  */,  
    unsigned    initial_val    /* in  */);
```

There are other approaches to solving this problem with mutexes.
POSIX also provides a somewhat different means of controlling
access to critical sections: semaphores.

```
int sem_destroy(sem_t*      semaphore_p /* in/out */);  
int sem_post(sem_t*        semaphore_p /* in/out */);  
int sem_wait(sem_t*        semaphore_p /* in/out */);
```

BARRIERS AND CONDITION VARIABLES

Barriers

- Synchronizing the threads to make sure that they all are at the same point in a program is called a barrier.
- No thread can cross the barrier until all the threads have reached it.

Using barriers to time the slowest thread

```
/* Shared */
double elapsed_time;
. . .
/* Private */
double my_start, my_finish, my_elapsed;
. . .
Synchronize threads;
Store current time in my_start;
/* Execute timed code */
. . .
Store current time in my_finish;
my_elapsed = my_finish - my_start;

elapsed = Maximum of my_elapsed values;
```

Using barriers for debugging

```
point in program we want to reach;  
barrier;  
if (my_rank == 0) {  
    printf("All threads reached this point\n");  
    fflush(stdout);  
}
```

Busy-waiting and a Mutex

- Implementing a barrier using busy-waiting and a mutex is straightforward.
- We use a shared counter protected by the mutex.
- When the counter indicates that every thread has entered the critical section, threads can leave the critical section.

Busy-waiting and a Mutex

```
/* Shared and initialized by the main thread */
```

```
int counter; /* Initialize to 0 */
```

```
int thread_count;
```

```
pthread_mutex_t barrier_mutex;
```

```
. . .
```

```
void* Thread_work(. . .) {
```

```
. . .
```

```
/* Barrier */
```

```
pthread_mutex_lock(&barrier_mutex);
```

```
counter++;
```

```
pthread_mutex_unlock(&barrier_mutex);
```

```
while (counter < thread_count);
```

```
. . .
```

```
}
```

We need one counter variable for each instance of the barrier, otherwise problems are likely to occur.

Implementing a barrier with semaphores

```
/* Shared variables */
int counter;          /* Initialize to 0 */
sem_t count_sem;      /* Initialize to 1 */
sem_t barrier_sem;    /* Initialize to 0 */
. . .
void* Thread_work(...) {
    . . .
    /* Barrier */
    sem_wait(&count_sem);
    if (counter == thread_count - 1) {
        counter = 0;
        sem_post(&count_sem);
        for (j = 0; j < thread_count - 1; j++)
            sem_post(&barrier_sem);
    } else {
        counter++;
        sem_post(&count_sem);
        sem_wait(&barrier_sem);
    }
    . . .
}
```

this implementation of a barrier is superior to the busy-wait barrier, since the threads don't need to consume CPU cycles when they're blocked in sem wait.

Can we reuse the data structures from the first barrier if we want to execute a second barrier?

Condition Variables

- A condition variable is a data object that allows a thread to suspend execution until a certain event or condition occurs.
- When the event or condition occurs another thread can signal the thread to “wake up.”
- A condition variable is always associated with a mutex.

Condition Variables

```
lock mutex;  
if condition has occurred  
    signal thread(s);  
else {  
    unlock the mutex and block;  
    /* when thread is unblocked, mutex is relocked */  
}  
unlock mutex;
```

Implementing a barrier with condition variables

```
/* Shared */
int counter = 0;
pthread_mutex_t mutex;
pthread_cond_t cond_var;
. . .
void* Thread_work(. . .) {
    . . .
    /* Barrier */
    pthread_mutex_lock(&mutex);
    counter++;
    if (counter == thread_count) {
        counter = 0;
        pthread_cond_broadcast(&cond_var);
    } else {
        while (pthread_cond_wait(&cond_var, &mutex) != 0);
    }
    pthread_mutex_unlock(&mutex);
    . . .
}
```

Like mutexes and semaphores, condition variables should be initialized and destroyed.

```
int pthread_cond_init(
pthread_cond_t *cond_p /* out */,
const pthread_condattr_t*condattr_p /* in */);
```

```
int
pthread_cond_destroy(
pthread_cond_t cond_p /* in/out */);
```

READ-WRITE LOCKS

Controlling access to a large, shared data structure

- Let's look at an example.
- Suppose the shared data structure is a sorted linked list of ints, and the operations of interest are Member, Insert, and Delete.

Linked Lists

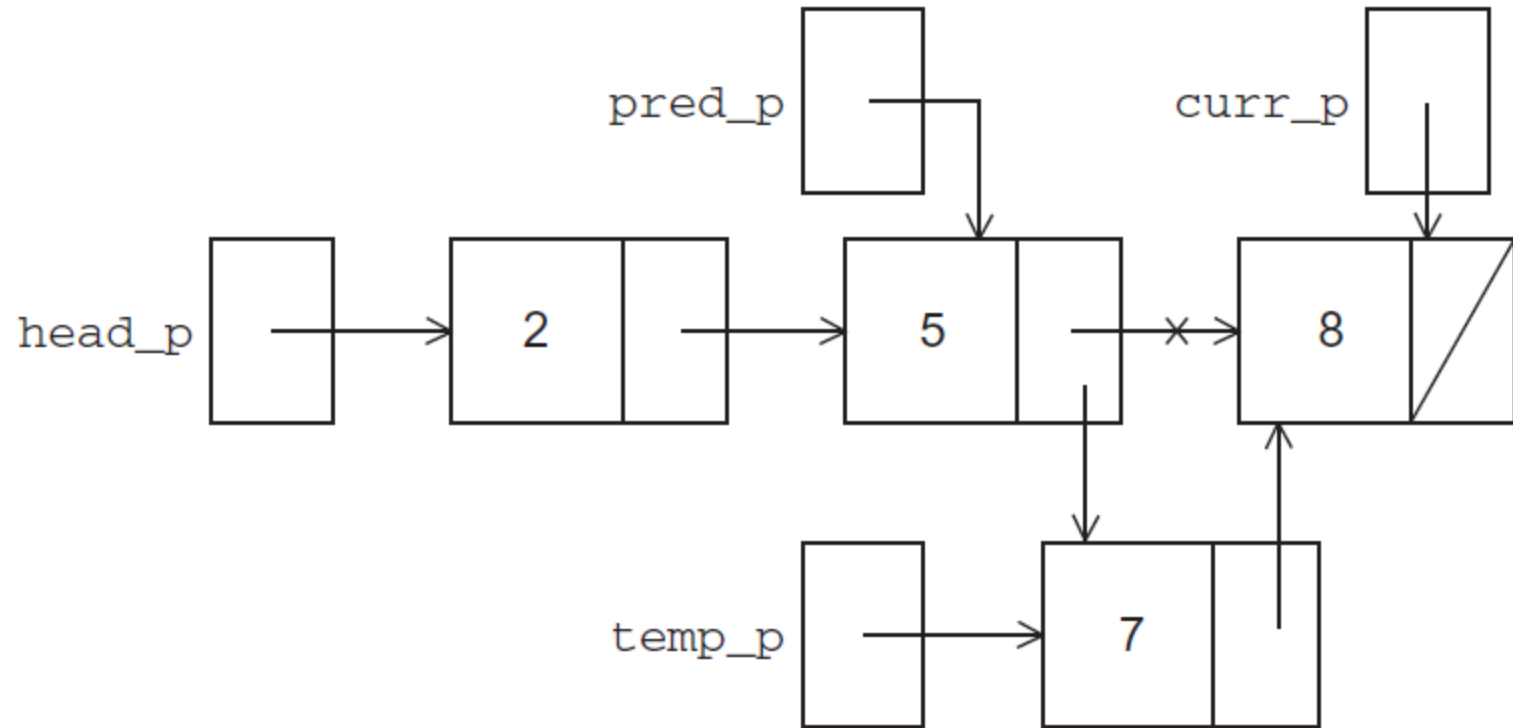

```
struct list_node_s {  
    int data;  
    struct list_node_s* next;  
}
```

Linked List Membership

```
int  Member(int value, struct list_node_s* head_p) {  
    struct list_node_s* curr_p = head_p;  
  
    while (curr_p != NULL && curr_p->data < value)  
        curr_p = curr_p->next;  
  
    if (curr_p == NULL || curr_p->data > value) {  
        return 0;  
    } else {  
        return 1;  
    }  
} /* Member */
```

Inserting a new node into a list

Inserting a new node into a list

```
int Insert(int value, struct list_node_s** head_pp) {
    struct list_node_s* curr_p = *head_pp;
    struct list_node_s* pred_p = NULL;
    struct list_node_s* temp_p;

    while (curr_p != NULL && curr_p->data < value) {
        pred_p = curr_p;
        curr_p = curr_p->next;
    }

    if (curr_p == NULL || curr_p->data > value) {
        temp_p = malloc(sizeof(struct list_node_s));
        temp_p->data = value;
        temp_p->next = curr_p;
        if (pred_p == NULL) /* New first node */
            *head_pp = temp_p;
        else
            pred_p->next = temp_p;
        return 1;
    } else { /* Value already in list */
        return 0;
    }
} /* Insert */
```

Deleting a node from a linked list

Deleting a node from a linked list

```
int Delete(int value, struct list_node_s** head_pp) {
    struct list_node_s* curr_p = *head_pp;
    struct list_node_s* pred_p = NULL;

    while (curr_p != NULL && curr_p->data < value) {
        pred_p = curr_p;
        curr_p = curr_p->next;
    }

    if (curr_p != NULL && curr_p->data == value) {
        if (pred_p == NULL) { /* Deleting first node in list */
            *head_pp = curr_p->next;
            free(curr_p);
        } else {
            pred_p->next = curr_p->next;
            free(curr_p);
        }
        return 1;
    } else { /* Value isn't in list */
        return 0;
    }
} /* Delete */
```

A Multi-Threaded Linked List

- Let's try to use these functions in a Pthreads program.
- In order to share access to the list, we can define `head_p` to be a global variable.
- This will simplify the function headers for `Member`, `Insert`, and `Delete`, since we won't need to pass in either `head_p` or a pointer to `head_p`: we'll only need to pass in the value of interest.

Simultaneous access by two threads

Solution #1

- An obvious solution is to simply lock the list any time that a thread attempts to access it.
- A call to each of the three functions can be protected by a mutex.

```
Pthread_mutex_lock(&list_mutex);  
Member(value);  
Pthread_mutex_unlock(&list_mutex);
```

In place of calling Member(value).

Issues

- We're serializing access to the list.
- If the vast majority of our operations are calls to **Member**, we'll fail to exploit this opportunity for parallelism.
- On the other hand, if most of our operations are calls to **Insert** and **Delete**, then this may be the best solution since we'll need to serialize access to the list for most of the operations, and this solution will certainly be easy to implement.

Solution #2

- Instead of locking the entire list, we could try to lock individual nodes.
- A “finer-grained” approach.

```
struct list_node_s {  
    int data;  
    struct list_node_s* next;  
    pthread_mutex_t mutex;  
}
```

Issues

- This is much more complex than the original **Member** function.
- It is also much slower, since, in general, each time a node is accessed, a mutex must be locked and unlocked.
- The addition of a mutex field to each node will substantially increase the amount of storage needed for the list.

Implementation of Member with one mutex per list node (1)

```
int Member(int value) {  
    struct list_node_s* temp_p;  
  
    pthread_mutex_lock(&head_p_mutex);  
    temp_p = head_p;  
    while (temp_p != NULL && temp_p->data < value) {  
        if (temp_p->next != NULL)  
            pthread_mutex_lock(&(temp_p->next->mutex));  
        if (temp_p == head_p)  
            pthread_mutex_unlock(&head_p_mutex);  
        pthread_mutex_unlock(&(temp_p->mutex));  
        temp_p = temp_p->next;  
    }  
}
```

Implementation of Member with one mutex per list node (2)

```
if (temp_p == NULL || temp_p->data > value) {
    if (temp_p == head_p)
        pthread_mutex_unlock(&head_p_mutex);
    if (temp_p != NULL)
        pthread_mutex_unlock(&(temp_p->mutex));
    return 0;
} else {
    if (temp_p == head_p)
        pthread_mutex_unlock(&head_p_mutex);
    pthread_mutex_unlock(&(temp_p->mutex));
    return 1;
}
} /* Member */
```

Pthreads Read-Write Locks

- Neither of our multi-threaded linked lists exploits the potential for simultaneous access to any node by threads that are executing Member.
- The first solution only allows one thread to access the entire list at any instant.
- The second only allows one thread to access any given node at any instant.

Pthreads Read-Write Locks

- A read-write lock is somewhat like a mutex except that it provides two lock functions.
- The first lock function locks the read-write lock for reading, while the second locks it for writing.

Pthreads Read-Write Locks

- So multiple threads can simultaneously obtain the lock by calling the read-lock function, while only one thread can obtain the lock by calling the write-lock function.
- Thus, if any threads own the lock for reading, any threads that want to obtain the lock for writing will block in the call to the write-lock function.

Pthreads Read-Write Locks

- If any thread owns the lock for writing, any threads that want to obtain the lock for reading or writing will block in their respective locking functions.

Protecting our linked list functions

```
pthread_rwlock_rdlock(&rwlock);
Member(value);
pthread_rwlock_unlock(&rwlock);
. . .
pthread_rwlock_wrlock(&rwlock);
Insert(value);
pthread_rwlock_unlock(&rwlock);
. . .
pthread_rwlock_wrlock(&rwlock);
Delete(value);
pthread_rwlock_unlock(&rwlock);
```

Linked List Performance

Implementation	Number of Threads			
	1	2	4	8

Caches, Cache-Coherence, and False Sharing

- Recall that chip designers have added blocks of relatively fast memory to processors called cache memory.
- The use of cache memory can have a huge impact on shared-memory.
- A write-miss occurs when a core tries to update a variable that's not in cache, and it has to access main memory.

Pthreads matrix-vector multiplication

```
void *Pth_mat_vect(void* rank) {
    long my_rank = (long) rank;
    int i, j;
    int local_m = m/thread_count;
    int my_first_row = my_rank*local_m;
    int my_last_row = (my_rank+1)*local_m - 1;

    for (i = my_first_row; i <= my_last_row; i++) {
        y[i] = 0.0;
        for (j = 0; j < n; j++)
            y[i] += A[i][j]*x[j];
    }

    return NULL;
} /* Pth_mat_vect */
```

Run-times and efficiencies of matrix-vector multiplication

Threads	Matrix Dimension					
	8,000,000 × 8		8000 × 8000		8 × 8,000,000	
	Time	Eff.	Time	Eff.	Time	Eff.
1	0.393	1.000	0.345	1.000	0.441	1.000
2	0.217	0.906	0.188	0.918	0.300	0.735
4	0.139	0.707	0.115	0.750	0.388	0.290

(times are in seconds)

THREAD-SAFETY

Thread-Safety

- A block of code is **thread-safe** if it can be simultaneously executed by multiple threads without causing problems.

Example

- Suppose we want to use multiple threads to “tokenize” a file that consists of ordinary English text.
- The tokens are just contiguous sequences of characters separated from the rest of the text by white-space — a space, a tab, or a newline.

Simple approach

- Divide the input file into lines of text and assign the lines to the threads in a round-robin fashion.
- The first line goes to thread 0, the second goes to thread 1, . . . , the t th goes to thread t , the $t + 1$ st goes to thread 0, etc.

Simple approach

- We can serialize access to the lines of input using semaphores.
- After a thread has read a single line of input, it can tokenize the line using the `strtok` function.

The strtok function

- The first time it's called the string argument should be the text to be tokenized.
 - Our line of input.
- For subsequent calls, the first argument should be NULL

```
char* strtok(  
    char*      string      /* in/out */,  
    const char* separators /* in      */);
```

The strtok function

- The idea is that in the first call, `strtok` caches a pointer to string, and for subsequent calls it returns successive tokens taken from the cached copy.

Multi-threaded tokenizer (1)

```
void *Tokenize(void* rank) {  
    long my_rank = (long) rank;  
    int count;  
    int next = (my_rank + 1) % thread_count;  
    char *fg_rv;  
    char my_line[MAX];  
    char *my_string;  
  
    sem_wait(&sems[my_rank]);  
    fg_rv = fgets(my_line, MAX, stdin);  
    sem_post(&sems[next]);  
    while (fg_rv != NULL) {  
        printf("Thread %ld > my line = %s", my_rank, my_line);
```

Multi-threaded tokenizer (2)

```
count = 0;
my_string = strtok(my_line, " \t\n");
while ( my_string != NULL ) {
    count++;
    printf("Thread %ld > string %d = %s\n", my_rank, count,
        my_string);
    my_string = strtok(NULL, " \t\n");
}

sem_wait(&sems[my_rank]);
fg_rv = fgets(my_line, MAX, stdin);
sem_post(&sems[next]);
}

return NULL;
} /* Tokenize */
```

Running with one thread

- It correctly tokenizes the input stream.

Pease porridge hot.

Pease porridge cold.

Pease porridge in the pot

Nine days old.

Running with two threads

```
Thread 0 > my line = Pease porridge hot.  
Thread 0 > string 1 = Pease  
Thread 0 > string 2 = porridge  
Thread 0 > string 3 = hot.  
Thread 1 > my line = Pease porridge cold.  
Thread 0 > my line = Pease porridge in the pot  
Thread 0 > string 1 = Pease  
Thread 0 > string 2 = porridge  
Thread 0 > string 3 = in  
Thread 0 > string 4 = the  
Thread 0 > string 5 = pot  
Thread 1 > string 1 = Pease  
Thread 1 > my line = Nine days old.  
Thread 1 > string 1 = Nine  
Thread 1 > string 2 = days  
Thread 1 > string 3 = old.
```

Oops!

What happened?

- `strtok` caches the input line by declaring a variable to have static storage class.
- This causes the value stored in this variable to persist from one call to the next.
- Unfortunately for us, this cached string is shared, not private.

What happened?

- Thus, thread 0's call to `strtok` with the third line of the input has apparently overwritten the contents of thread 1's call with the second line.
- So the `strtok` function is not thread-safe. If multiple threads call it simultaneously, the output may not be correct.

Other unsafe C library functions

- Regrettably, it's not uncommon for C library functions to fail to be thread-safe.
- The random number generator `random` in `stdlib.h`.
- The time conversion function `localtime` in `time.h`.

“re-entrant” (thread safe) functions

- In some cases, the C standard specifies an alternate, thread-safe, version of a function.

```
char* strtok_r(  
    char*      string      /* in/out */,  
    const char* separators, /* in    */,  
    char**     saveptr_p   /* in/out */);
```

Concluding Remarks (1)

- A thread in shared-memory programming is analogous to a process in distributed memory programming.
- However, a thread is often lighter-weight than a full-fledged process.
- In Pthreads programs, all the threads have access to global variables, while local variables usually are private to the thread running the function.

Concluding Remarks (2)

- When indeterminacy results from multiple threads attempting to access a shared resource such as a shared variable or a shared file, at least one of the accesses is an update, and the accesses can result in an error, we have a **race condition**.

Concluding Remarks (3)

- A **critical section** is a block of code that updates a shared resource that can only be updated by one thread at a time.
- So the execution of code in a critical section should, effectively, be executed as serial code.

Concluding Remarks (4)

- **Busy-waiting** can be used to avoid conflicting access to critical sections with a flag variable and a while-loop with an empty body.
- It can be very wasteful of CPU cycles.
- It can also be unreliable if compiler optimization is turned on.

Concluding Remarks (5)

- A **mutex** can be used to avoid conflicting access to critical sections as well.
- Think of it as a lock on a critical section, since mutexes arrange for mutually exclusive access to a critical section.

Concluding Remarks (6)

- A **semaphore** is the third way to avoid conflicting access to critical sections.
- It is an unsigned int together with two operations: `sem_wait` and `sem_post`.
- Semaphores are more powerful than mutexes since they can be initialized to any nonnegative value.

Concluding Remarks (7)

- A **barrier** is a point in a program at which the threads block until all of the threads have reached it.
- A **read-write lock** is used when it's safe for multiple threads to simultaneously read a data structure, but if a thread needs to modify or write to the data structure, then only that thread can access the data structure during the modification.

Concluding Remarks (8)

- Some C functions cache data between calls by declaring variables to be static, causing errors when multiple threads call the function.
- This type of function is not **thread-safe**.
